Domain-Driven Design

CS 618 Feb 21, 2012 Bill Kidwell

Domain-Driven Design

- Software models some aspect of the real world
- We build design models to understand what we are building, and how we will build it
- Symmetry between our software, design model, and the real world allow us to adjust to changes in the real world

Ubiquitous Language

- A common language between the domain experts and the developers
- The Domain model should be based heavily on the Ubiquitous Language
- Discussion Point:
 - How does common language help with technical decisions? Examples?

UL ties the models together

CS618

- Tie the Implementation to the Model
- Provide tools that make this efficient
 - E.g. round trip reverse engineering tools
- Developers and Modelers are tightly coupled with this approach

Navigation Map

Entities

- Have an identity
 - Not the address of the object
 - What is the identity?
 - Consider two person objects, same name, same date of birth separate identities
 - We often generate an identifier
 - Account Number

Value Objects

- Not all objects are entities!
 - We can't justify the overhead of creating and tracking identities for all objects
- It is recommended that value objects be immutable
- Examples of possible Value objects
 - Money/Currency class
 - Point class in a drawing application
 - Address class ?

Services

- Some aspects of the domain don't map easily to objects
- A Service is some behavior, that is important to the domain, but does not "belong" to an Entity or Value object
- Example: Account Transfer
- Encapsulate an important domain concept
 - NOTE: Not just for technical infrastructure

Characteristics of Services

- 1. The operation performed by the Service refers to a domain concept which does not naturally belong to an Entity or Value Object.
- 2. The operation performed refers to other objects in the domain.
- 3. The operation is stateless.

Aggregates

- A group of associated objects which are considered as a unit with regard to data changes
- An aggregate should have one root
- The root is an entity object
- Outside objects can reference root, but not the other members of the aggregate

Aggregate Root Example

PO Example (from Evans)

PO Example (cont'd)

- Parts are used in many Pos (high contention)
- Fewer changes to parts than Pos
- Changes to part prices do not necessarily propagate to existing POs

PO Example (cont'd)

Factories

- Encapsulate the information necessary for object creation
 - Includes logic for all creating all the members of an aggregate
 - Allows us to enforce invariants during creation
 - Related GoF Design Patterns
 - Factory Method, Abstract Factory
 - Designing the Factory Interface
 - Each operation must be atomic
 - The Factory will be coupled to its arguments

Repositories

- Encapsulates logic to obtain object references
- Provides a mechanism to persist/retrieve an object
 - Keeps persistence code out of the domain layer
- Repository interface should be driven by the domain model
- Repository implementation will be closely linked to the infrastructure

Repositories

Building Complex Specifications
