Do We Know This Already?

- We saw the basics of experimental design in 5th grade
 - Not many details
 - Many of us were not paying attention
- College students in science learn this in their freshman year
 - Physics, chemistry, biology, ...

A <u>major failing</u> of CS is that we do not teach this material

Descriptive Research

Used to discover trends and tendencies

- <u>Observational studies</u>: systematic measurement of behavior
 - interrater reliability: degree to which independent observers agree on their coding of data
- <u>Archival studies</u>: examine records of past events and behaviors
- <u>Surveys</u>: asking questions about attitudes, beliefs, and behavior

3

Scientific Experiment

Used to understand effects

- Changes a set of variables to elicit a response
- Imposes a <u>treatment</u> on a group of *objects* or subjects
 - Treatment defines a way to change variables

© Jeff Offutt, 2005

Correlational Research

Used to establish associations between variables

- <u>Correlation coefficient</u>: statistical measure of the strength and direction of association between two variables (varies between -1.0 and +1.0)
 - <u>Positive correlation</u>: As one variable increases the other also increases
 - Negative correlation: As one variable increases the other decreases

© Jeff Offutt, 2005

5

Basic Experimental Terms

- <u>Hypothesis</u>: A testable prediction about the conditions under which an event will occur
- <u>Theory</u>: An organized set of principles used to explain observed phenomena
- <u>Operational Definition</u>: A specific way in which a variable is measured or manipulated (*treatment*)

© Jeff Offutt, 2005

Variables

- <u>Independent variable</u>: manipulated by the researcher to determine if it causes a change in the dependent variable
 - Also called *factor*
- <u>Dependent variable</u>: measured by the researcher to determine if it is affected by the IV
- <u>Confounding variables</u>: alternative explanations for the results
- <u>Measured variable</u>: If the dependent variable cannot be directly measured, we measure a related variable to approximate

© Jeff Offutt, 2005

7

Validity

- <u>Internal validity</u>: degree to which there is certainty that the IV caused the effects on the DV
- <u>External validity</u>: degree to which the results from a study can be generalized to other situations and people
- <u>Conclusion validity</u>: degree to which conclusions relationships in the data are reasonable
- <u>Construct validity</u>: degree to which inferences can be made from the specific objects in your study to the theoretical constructs on which those objects were based

© Jeff Offutt, 200

Experimental Bias

- <u>Bias</u>: A flaw in the experimental design or conduct that can change the dependent variable
 - This is often due to an inadvertent introduction of a confounding variable
- <u>Bias (psychology)</u>: A flaw introduced by an experimenter whose expectations about the outcome of the experiment can be subtly communicated to the participants in the experiment
 - Often happens when experimenters are also subjects

© Jeff Offutt, 2005

9

Example

Data flow testing finds more faults than branch testing

- Independent Variables: Data flow, branch testing
- Dependent Variable: Faults found
- Confounding Variables: tool support, characteristics of subjects, specific values chosen, knowledge of testers, ...
 - Effects the internal validity
- Bias: If I invented data flow, I expect it to do better

© Jeff Offutt, 2005

Correlation and Causality

- Correlated: Two things always happen at the same time
 - Brake lights and car slowing down
- *Causality*: Understanding what causes something to happen
 - Brake light causes the car to slow down
- If A and B are correlated:
 - A causes B
 - B causes A
 - C causes A and B
 - Pressing brake activates brake light AND slows car down

© Jeff Offutt, 2005

11

Confusing Correlation and Causality

- In "the old days", we believed that being <u>cold</u> caused us to get <u>colds</u>
- Colds are caused by <u>viruses</u>, not temperature
- Viruses breed very well in <u>warm</u>, <u>damp</u>, <u>low-oxygen</u>, <u>carbon-dioxide rich</u> environments
- When the weather turns cold, we often <u>close</u> up our houses and <u>turn up the heat</u> ... creating ...
- In Virginia, we have a <u>secondary cold season</u> in July-August ... when the weather turns hot and humid ...

© Jeff Offutt, 2005

Cognitive Dissonance

- We feel uncomfortable when new data or a new model contradicts a previously held model
- Revising our mental model to accommodate new data is hard
 - We resist the new idea

© Jeff Offutt, 2005

13

Correlation and Prediction

- Correlation: if A happens, then B happens
 - Brake lights and car slowing down
- Causality: if A happens, then it causes B to happen
 - Pressing brake slows the car down
- <u>Predictability</u>: if A happens, I can predict that B will happen

We do <u>not</u> need to show causality to have predictability

© Jeff Offutt, 2005

Experimental Design

- Choosing variables, subjects, objects, process and analysis method
- <u>Pilot study</u>: small-scale experiment used to design the full experiment
 - Identify potential confounding variables
 - Refine experimental design

© Jeff Offutt, 2005

15

Avoiding Bias in Experimental Design

- <u>Control</u>: Ensuring the confounding variables do not influence the results
 - I want to measure whether maintenance programmers understand programs better by studying <u>statecharts</u> or reading <u>comments</u>
 - Comments <u>already existed</u> in the program, statecharts generated by <u>experimenter</u>
 - Statecharts were of much <u>higher quality</u>
 - Programmers understood statecharts better ...
- Must control for differences in quality

© Jeff Offutt, 2005

Placebos in Experimental Design

- Patients expect a treatment to work, and sometimes respond to a treatment that has no effect – like a sugar pill
- Programmers in an experiment will do better because they think they should they concentrate better or work harder
 - Give some programmers a tool that actually does not work
- <u>Double-blind</u>: Neither the programmers or the experimenter knows who has the placebo

© Jeff Offutt, 2005

17

Hawthorne Effect

- When people know they are being studied, they will behave differently
- How can we study people without letting them know they are being studied?

© Jeff Offutt, 2009

- <u>Randomization</u>: Objects are assigned randomly to experimental groups
 - Randomized block design: Divide subjects into homogeneous blocks, then randomly assign from each block
 - Programmers: undergraduate students, MS students, PhD students, professional
- <u>Replication</u>: perform the experiment again, with different subjects, experimenters, or experiment design
 - Most reviewers will not accept replicated experiments
